PRELIMINARY AMENDMENTBOX PATENT APPLICATION
Assistant Commissioner for Patents
Washington, D.C. 20231

Dear Sir:

This Preliminary Amendment is being filed concurrently with a 1.53(b) Continuation Application, based upon Serial No. 08/793,956; filed March 12, 1997, which was filed from International Application No. PCT/FR95/01158; filed September 11, 1995.

Entry of the following amendments prior to examination of the application is respectfully requested.

IN THE SPECIFICATION:

At page 1, before the heading "DESCRIPTION", please insert:

--RELATED APPLICATIONS:

This is a continuation of Serial No. 08/793,956, filed March 12, 1997.--

IN THE CLAIMS:

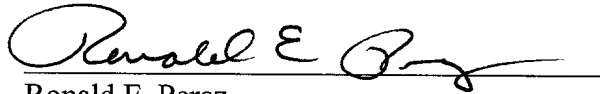

Please cancel claims 2 to 15, without prejudice.

REMARKS

A subsequent preliminary amendment will be filed to add the claims for this continuation application.

Respectfully submitted,

FULWIDER PATTON LEE & UTECHT, LLP

Pressure-controlled breathing aid

DESCRIPTION

The present invention relates to a pressure-controlled breathing aid.

5 Breathing aid devices - or ventilation devices - currently used in mechanical ventilation can be divided into two main groups, namely volumetric devices characterized by the supply of a specified volume in each respiratory cycle, and pressure-controlled devices
10 characterized by the provision of a specified pressure in each respiratory cycle.

Volumetric devices have the advantage of guaranteeing a specified breathed volume, but they have major disadvantages. In particular, they expose the
15 patient to risks of barotrauma as they tend to apply pressure which increases at the end of insufflation. Furthermore, the patient risks not being matched to the device in the sense that the respiratory reflexes of the patient can appear at different times from those at
20 which the volumes imposed by the device finish being supplied.

On the contrary, pressure-controlled devices allow better synchronization of the patient with the device and avoid the risk of barotrauma since the maximum
25 pressure supplied is known in advance. On the other hand, the volume supplied to the patient in each cycle and the breathed volume are not guaranteed.

The purpose of the present invention is to propose a breathing aid device which combines the advantages of
30 both of the known ventilation modes discussed above.

According to the invention, the pressure mode breathing aid device, comprising means for supplying breathable gas to an inspiratory branch of a patient

Express Mail No. EL372192158 US

09307541.050799
66050 TFS/050

circuit at an inspiratory pressure, is characterized by:

- means of measuring the breathed volume,
- means of comparing the breathed volume with a command, and
- 5 - regulation means to increase the inspiratory pressure in the case of a breathed volume lower than the command, and to reduce the inspiratory pressure in the case of a breathed volume higher than the command.

10 Thus, the pressure is adjusted in a direction tending to provide the predetermined volume applied as a command. In this way a volume is guaranteed without taking the risk of increasing the pressure in an uncontrolled manner, nor of creating the particular risk
15 of mismatch between the breathing timing of the patient and that of the device. In particular, the invention is perfectly compatible with devices of the type described in FR-A-2 695 830 in which the device detects the respiratory reflexes of the patient in order to change
20 from inspiratory phases to expiratory phases and vice-versa.

 In order to prevent any risk of barotrauma, it is advantageous to provide means of setting a maximum predetermined pressure which the pressure applied to the
25 patient will not be able to exceed even if the volume supplied is insufficient.

 It is also advantageous to provide a signalling device or other alarm detecting the simultaneous occurrence of insufficient volume and the setting of the
30 pressure at its maximum predetermined value, in order to signal this situation of the device's inability to provide the breathed volume set as a command.

 In the framework of the present invention, the expression "breathed volume" is used to denote both the
35 volume of the breathable gas inspired or expired per

Preferably, the adjustment means apply to the inspiratory pressure a pressure variation which is equal in percentage to the difference between the inspiratory volume and the command.

Other features and advantageous of the invention will furthermore emerge from the following description relating to non-limitative examples.

- Figure 1 is a block diagram of a first embodiment of the device according to the invention;

20 Figures 3 and 4 are two block diagrams similar to
Figure 1 but relating to two embodiments of the device
according invention.

In the example shown in Figure 1, the breathing aid device comprises a patient circuit 1 which itself comprises a patient connection 2, namely a facial or nasal mask, or an intubation or tracheotomy tube, connected to an inspiratory branch 3 and to an expiratory branch 4 by the intermediary of a bidirectional branch 5. The expiratory branch 4 comprises an expiration device 6 which, in a way which is not shown, comprises an expiration valve and means of controlling this valve. The expiration valve is closed during the inspiratory phases of the patient's breathing. During the expiratory phases of the patient's breathing, the expiration valve can either be open so that the patient expires at atmospheric

pressure, or it can operate like a discharge valve to oblige the patient to expire at a certain predetermined excess pressure.

5 The inspiratory branch 3 is connected, at its end
furthermost from the mask 2, to a unit 8 for ventilation
through inspiratory aid which comprises means, such as
an adjustable speed motor-turbine set, for supplying
breathable gas through the inspiratory branch 3 at an
adjustable pressure, in the direction of the mask 2,
10 means of detecting the patient's respiratory reflexes,
for example from instantaneous flow rate variations, and
means of controlling the expiration valve of the
expiration means 6 and an inspiration valve placed in
the inspiratory branch 3 in order to open the
15 inspiration valve and to close the expiration valve
during the inspiratory phase, and to close the
inspiration valve and to release the expiration valve
during the expiratory phases. Thus, in the inspiratory
phase, the patient is connected in a gas-tight manner
20 with the inspiratory branch 3, and the volume flowing in
the inspiratory branch 3 corresponds to the volume of
gas inspired. And during the expiratory phases, the
patient is connected in a gas-tight manner with the
expiratory branch 4 and the volume flowing in the
25 expiratory branch 4 corresponds to the volume of gas
expired.

Such inspiratory aid devices, or inspiratory aid
devices of the same kind are described in the prior art,
in particular in FR-A-2 695 830.

30 The ventilation unit 8 can comprise pressure
control means by means of which the pressure P detected
in the inspiratory branch 3 by a detector 10 is compared
with a pressure command AI in order to adjust, for
example, the speed of rotation of the motor-turbine set
35 in the direction tending to make the pressure P equal to
the command AI.

According to the invention, the breathing aid device comprises means 11 of regulating the patient's breathed volume. The regulating means 11 comprise a control unit 9 for controlling the pressure command AI which the ventilation unit 8 must apply to the inspiratory branch 3 during the inspiratory phases.

The regulating means 11 furthermore comprise a unit 12 for measuring the volume VTI inspired by the patient during each breathing cycle. The unit 12 provides the control unit 9 with a signal indicative of the volume VTI. The control unit 9 comprises an input 13 for receiving the signal VTI, and three inputs 14, 16, 17, allowing the user of the device to enter a minimum breathed volume command into the control unit, in the form of a minimum inspired volume per cycle VTImini, a minimum inspiratory pressure command AImini, and a maximum inspiratory pressure command AImaxi.

In general, the control unit 9 compares the measured volume VTI with the command VTImini and adjusts the pressure command AI in the direction tending to bring the measured volume VTI towards the command VTImini, without however causing the command AI to move outside of the range included between the two extreme values AImini and AImaxi. Within this range, the control unit 9 tends to increase the command AI when the measured volume VTI is lower than the command VTImini, and to reduce the pressure command AI in the opposite case.

When starting up the device, the commands VTImini and AImini are chosen such that the breathed volume VTI is established at a value higher than VTImini when the pressure command AI is equal to AImini. Thus, if the patient breathes as expected, the pressure command AI stabilises at AImini with a breathed volume above the minimum command VTImini. It is only in the event of a

5 generated by the control unit 9. When the breathing becomes normal again, the breathed volume again becomes higher than the command VTImini, such that the control unit 9 returns the pressure command AI more or less rapidly to the value AImini.

10 The flowchart used by the control unit 9 will now
be described in greater detail with reference to Figure
2. At the start, A1 is made to equal to AImini (step
18).

Then, at the end of each breathing cycle, or during each expiratory phase, the measurement VTI of the volume inspired during the preceding inspiratory phase is acquired (step 19) and is then compared with the command VTImini by the test 21. If the measured volume VTI is greater than or equal to VTImini, in other words if the volume inspired by the patient is satisfactory, a test 22 determines if the pressure command AI is or is not greater than the minimum AImini. If the pressure command is equal to the minimum, the conditions are therefore ideal (volume at least equal to the minimum, minimum pressure) and the sequence therefore returns directly to step 19 for acquiring the next inspired volume measurement. In the opposite case, advantage will be taken of the fact that the inspired volume is satisfactory in order to attempt to reduce the pressure command by a step 23 in which there is applied to the pressure command AI, expressed in relative value, a variation equal in percentage and opposite in sign to the difference between the measured inspired volume VTI and the command VTImini. The formula is such that, in the particular case in which the measured volume VTI is equal to VTImini, no modification is applied to the pressure command AI (0% variation).

Returning now to the test 21 on the measured volume VTI, if the latter is lower than the command VTImini, an attempt will be made to increase the pressure command AI in order to assist the patient more. But prior to this,
5 by a test 24, it will be checked that the pressure command AI has not already reached the maximum AI_{maxi}. If the answer is yes, an alarm is triggered (step 26) to indicate the necessity of an urgent intervention.

On the other hand, if the pressure command AI is
10 not yet equal to AI_{maxi}, the sequence returns as before to step 23 in which there will be applied to the command AI a variation equal in percentage and opposite in sign to the difference between the measured volume VTI and the command VTImini.

15 Before actually applying the command AI, reduced or increased such as it has been computed in step 23, to the input of the ventilation unit 8, it will firstly be checked, by a test 27, that the new computed AI value does not exceed the maximum AI_{maxi} and, by a test 28,
20 that it is not less than the minimum AI_{mini}.

If the new AI value has gone beyond one or other of these extreme values, the command AI which will be applied to the ventilation unit 8 will be equal to the extreme value in question (steps 29 and 31).

25 The example shown in Figure 3 will only be described where it differs with respect to the example shown in Figure 1.

In the example of Figure 3, the breathed volume is no longer measured by means of the volume inspired in
30 each cycle but by means of the volume VTE expired in each cycle. For this purpose, the VTI measuring unit 12 in the inspiratory branch 3 has been eliminated and it has been replaced by a VTE measuring unit 32 in the expiratory branch 4.

35 The minimum breathed volume command applied to the control unit 9 is therefore the command VTE_{mini} for the volume expired per cycle, in order to be able to be

664050"TT20680

compared directly with the measurement provided by the unit 32.

It can be advantageous to select, case by case, measurement of the inspired volume or measurement of the expired volume. This is the solution proposed by the embodiment shown in Figure 4, which will be described only where it differs with respect to the example shown in Figure 1.

The measuring unit 42 is this time installed in the bidirectional branch 5 of the patient circuit 1 and it comprises means 43 of selecting the direction of flow in which the volume is to be measured. In accordance with this selection, the unit 42 provides, by choice, a measurement of VTI or of VTE. In accordance with the operating mode of the measuring unit 42, the control unit 9 interprets the input applied at 14 as an inspired volume command or as an expired volume command. There is no longer any measuring unit in the inspiratory branch 3 nor in the expiratory branch 4.

In all of the described embodiments, the speed of execution of the flowchart in Figure 2 is sufficient for the measurement carried out in each breathing cycle to make it possible to correct the pressure applied during the following inspiratory phase. When the measurement is based on the expired volume, it is however possible that the pressure correction will occur only during, and not from the start, of the following inspiratory phase.

The invention is applicable to all ventilators capable of measuring the volumes delivered and of automatically controlling the value of the insufflation pressure.

The invention is applicable to all methods of ventilation using pressure control, and in particular to "inspiratory aid" and "controlled pressure" methods. Inspiratory aid is a method consisting in maintaining a substantially constant pressure in the patient circuit

It would also be conceivable for the control unit, instead of adjusting the pressure command AI applied to the ventilation unit, to adjust, for example, the speed of rotation of the motor turbine set, or the electrical power supplied to it. It would then be possible to avoid abnormal pressures in the inspiratory branch 3 by comparing the pressure in the inspiratory branch 3 with limits such as AImini and AImaxi, and by initiating a corrective modification of the speed or of the power of the motor turbine set in the case of exceeding, or of risk of exceeding such limits.

CLAIMS

1. Pressure mode breathing aid device, comprising means (8) for supplying breathable gas to an inspiratory branch (3) of a patient circuit (1) at an inspiratory pressure (AI), characterized by:

- means (12; 32; 42) of measuring the breathed volume (VTI, VTE),
- means of comparing the breathed volume (VTI; VTE) with a command (VTImini; VTEmini), and
- regulation means (11) to increase the inspiratory pressure (AI) in the case of a breathed volume lower than the command (VTImini; VTEmini), and to reduce the inspiratory pressure in the case of a breathed volume higher than the command (VTImini; VTEmini).

2. Device according to Claim 1, characterized in that in order to adjust the inspiratory pressure, the regulating means (11) adjust a pressure command applied to a regulated pressure ventilation unit (8).

3. Device according to Claim 1 or 2, characterized in that the means (12; 32; 42) for measuring the breathed volume measure the volume amount (VTI; VTE) which has been breathed by the patient during a breathing cycle, and the regulating means (11) are based on the result of the comparison (21) of this volume amount with the command in order to adjust the inspiratory pressure applied during a following cycle.

4. Device according to one of Claims 1 to 3, characterized in that the means (12; 42) of measuring the breathed volume measure the volume (VTI) inspired by the patient.

5. Device according to one of Claims 1 to 3, characterized in that the means (32; 42) of measuring

the breathed volume measure the volume (VTE) expired by the patient.

6. Device according to one of Claims 1 to 3, characterized in that the means (42) of measuring the
5 breathed volume selectively measure the volume inspired (VTI) or the volume expired (VTE) by the patient.

7. Device according to Claim 4, characterized in that it comprises means (8) for connecting the
10 inspiratory branch (3) in substantially gas-tight manner with the respiratory channels of the patient during inspiratory phases of the respiratory cycle and to interrupt the flow of breathable gas in the inspiratory branch (3) during expiratory phases of the respiratory cycle, and in that the means (12) of measuring the
15 breathed volume are connected to the inspiratory branch (3).

8. Device according to Claim 5, characterized in that the patient circuit (1) comprises an expiratory branch (4) and in that the device comprises means (5) of
20 connecting the expiratory branch (4) in a substantially gas-tight manner with the respiratory channels of the patient during expiratory phases of the respiratory cycle and to interrupt the flow of gas in the expiratory branch (4) during inspiratory phases of the respiratory
25 cycle, and in that the means (32) of measuring the breathed volume are connected to expiratory branch (4).

9. Device according to Claim 6, characterized in that the patient circuit (1) comprises a bidirectional branch (5) to which are connected the inspiratory branch
30 (3) and an expiration path (4), in that the means (42) of measuring the breathed volume are connected to the bidirectional branch and are capable of measuring the volume in both directions of flow, means (43) being provided to select the direction of the flow in which
35 the breathed volume measuring means (42) measure the volume.

03054.0509

10.Device according to one of Claims 1 to 9,
characterized in that the regulating means increase the
inspiratory pressure (AI) in the cases of a breathed
volume (VTI, VTE) less than the command where the
5 inspiratory pressure (AI) is less than a predetermined
maximum pressure (AI_{maxi}).

11.Device according to one of Claims 1 to 10
characterized in that the regulating means reduce the
inspiratory pressure (AI) in the cases of a breathed
10 volume (VTI, VTE) higher than the command where the
inspiratory pressure (AI) is greater than a
predetermined minimum pressure (AI_{mini}).

12.Device according to one of Claims 1 to 11,
characterized in that, in at least certain of the said
15 breathed volume (VTI; VTE) cases below and above the
command (VTI_{mini}; VTE_{mini}), the regulating means apply
to the inspiratory pressure a pressure variation which
increases with the difference between the measured
breathed volume (VTI, VTE) and the command (VTI_{mini},
20 VTE_{mini}).

13.Device according to one of Claims 1 to 11,
characterized in that, in at least certain of the said
breathed volume cases (VTI; VTE) below and above the
command (VTI_{mini}; VTE_{mini}) the regulating means apply to
25 the inspiratory pressure a pressure variation equal in
percentage to the difference between the measured
breathed volume (VTI; VTE) and the command (VTI_{mini}:
VTE_{mini}).

14.Device according to one of Claims 1 to 11,
30 characterized in that, in at least certain of the said
cases of breathed volume (VTI; VTE) below and above the
command (VTI_{mini}; VTE_{mini}), the regulating means compute
a modified pressure and apply the modified pressure if
the modified pressure does not go beyond a predetermined
35 extreme value and make the inspiratory pressure equal to
the predetermined extreme value if

the computed modified pressure goes beyond the predetermined extreme value.

15. Device according to Claim 10 or 14,
characterized in that it comprises a means (26) of
5 indicating the simultaneous occurrence of a breathed
volume (VTI; VTE) below the command (VTImini) and an
inspiratory pressure (AI) at least equal to a
predetermined maximum pressure.
